

Motivation

Real-time applications like robotics and augmented reality need to swiftly detect and respond to **complex events** as they unfold, beyond a limited set of predefined classes.

We introduce a novel task called Streaming Detection of Queried Event Start (SDQES), which leverages natural language to enable complex events descriptions in **streaming video**.

The goal of goal of SDQES is to output a high accuracy prediction of event start (*i.e.*, output time with high accuracy and low latency. We propose new metrics especially suited for measuring progress on this task: Streaming Recall and Streaming Minimum Distance.

$$egin{aligned} ext{SR}(k,W) &= rac{1}{|Q|} \sum_{q \in Q} \mathbf{1} \{ \exists t_{ ext{out}} \in P_M^{(k)} : -anticipation \leq t_s - t_{ ext{out}} \leq l \ & ext{SMD}(k) = rac{1}{|Q|} \sum_{q \in Q} \min_{t_{ ext{out}} \in P_M^{(k)}} |t_s - t_{ ext{out}}| \end{aligned}$$

The Challenge: there are no existing datasets for this task, and current ODAS streaming **models are limited**—they can only effectively output to a limited set of predefined classes.

Streaming Detection of Queried Event Start

latency

To address this, we develop a pipeline to generate a **new dataset for the task**, leveraging the Ego4D annotations to facilitate training and benchmarking of models for this capability.

Models: Streaming Adapters

Our proposed approach leverages pretrained vision-language foundation models by integrating parameter-efficient streaming adapters to deliver real-time, continuous event detection on **untrimmed video streams**.

We evaluate a variety of combinations of Streaming Adapters and dual-encoder visionlanguage models, including the current state-of-the-art (SOTA) egocentric video encoder.

Main takeaways include:

Main Results

We evaluate baselines on both short clips and extremely long untrimmed videos.

• Training on our dataset significantly improves performance on SDQES, with all adapted models finetunned on the generated data surpassing the zero-shot baseline. Streaming adapters with long temporal horizons outperform non-temporal models, proving that more **complex temporal modeling capabilities are beneficial** for SDQES.
